1

4 **Purpose of document**:

- 5 This document is intended to document the model structure and user-options available in
- 6 package VAST. For guidance and examples of how to use the model, please see the
- 7 Rmarkdown tutorials in the GitHub "/examples" directory. In the following, I try to use
- 8 notation similar to the TMB code: I use parentheses to indicate a parameter or variable that is
- 9 indexed by the specified indices, and I use subscripts for naming (e.g., to indicate different
- parameters for different model components). Feel free to change notation when describing
- the model to suite your purposes. For further details regarding terminology, motivation, and
- statistical properties, please read the papers listed on the GitHub main page.

13 Model description:

14 Linear predictors

- I use a delta-model that includes two linear predictors. The linear predictor for encounter
- 16 probability:

17
$$p_1(x_i, c_i, t_i) = \beta_1(c_i, t_i) + \sum_{f=1}^{n_{\omega 1}} L_{\omega 1}(c_i, f) \omega_1(s_i, f) + \sum_{f=1}^{n_{\varepsilon 1}} L_{\varepsilon 1}(c_i, f) \varepsilon_1(s_i, f, t_i)$$

18
$$+ \sum_{f=1}^{n_{\delta_1}} L_{\delta_1}(v_i, f) \delta_1(v_i, f) + \sum_{p=1}^{n_p} \gamma_1(c_i, t_i, p) X(x_i, t_i, p) + \sum_{k=1}^{n_k} \lambda_1(k) Q(i, k)$$

- where $p(s_i, c_i, t_i)$ is the predictor for cell x_i in the extrapolation grid for observation i,
- 20 $\beta_1(c_i, t_i)$ is an intercept for category c_i and year t_i , $\omega_1(s_i, f)$ represents spatial variation and
- 21 $L_{\omega 1}(c_i, f)$ is the loadings matrix that generates spatial covariation among categories for this
- linear predictor, $\varepsilon_1(s_i, f, t_i)$ is spatio-temporal variation and $L_{\varepsilon_1}(c_i, f)$ is the loadings matrix

that generates spatio-temporal covariation for this predictor, $\delta_1(v_i, f)$ is random variation in catchability among a grouping variable (tows or vessels) and $L_{\delta 1}(v_i, f)$ is a loadings matrix that generates covariation in catchability among categories for this predictor, $X(x_i, t_i, p)$ are measured density covariates that explain variation in density and $\gamma_1(c_i, t_i, p)$ is the estimated impact of density covariates, and Q(i, k) are measured catchability covariates that explain variation in catchability and $\lambda_1(k)$ is the estimated impact of catchability covariates for this linear predictor. Similarly, the linear predictor for positive catch rates:

30
$$p_2(x_i, c_i, t_i) = \beta_2(c_i, t_i) + \sum_{f=1}^{n_{\omega 1}} L_{\omega 2}(c_i, f) \omega_1(s_i, f) + \sum_{f=1}^{n_{\varepsilon 1}} L_{\varepsilon 2}(c_i, f) \varepsilon_2(s_i, f, t_i)$$

$$+\sum_{f=1}^{n_{\delta_1}} L_{\delta_2}(v_i, f) \delta_2(v_i, f) + \sum_{p=1}^{n_p} \gamma_2(c_i, t_i, p) X(x_i, t_i, p) + \sum_{k=1}^{n_k} \lambda_2(k) Q(i, k)$$

where all variables and parameters are defined similarly except using different subscripts.

The user controls the number of spatial and spatio-temporal factors used for each component via input:

```
# Control number of factors
FieldConfig = c("Omega1"=1, "Epsilon1"=1, "Omega2"=1, "Epsilon2"=1)
37
```

38 where FieldConfig[1] controls $n_{\omega 1}$, FieldConfig[2] controls $n_{\varepsilon 1}$, FieldConfig[3] controls

 $n_{\omega 2}$, and FieldConfig[4] controls $n_{\varepsilon 2}$, and a value of zero "turns off" that component of

spatial or spatio-temporal covariation. The user controls the number of catchability factors

41 used for each component via input:

```
# Control number of spatial and spatio-temporal factors
OverdispersionConfig = c("Delta1"=0, "Delta2"=0)
```

where OverdispersionConfig[1] controls $n_{\delta 1}$, and OverdispersionConfig[2] controls $n_{\delta 2}$,

and a value of zero again "turns off" that component of random covariation in catchability.

Link functions

33

34

39

40

44

- There are different user-controlled options for link-functions that calculate expected
- 49 encounter probability and positive catch rates given these two linear predictors.
- # Control number of catchability factors
- OverdispersionConfig = c("Vessel"=0, "VesselYear"=0)

52

- where the 2^{nd} element of this vector controls the link functions. ObsModelp[2]=0 corresponds
- to a conventional delta-model:

55
$$r_1(x_i, c_i, t_i) = logit^{-1}(p_1(x_i, c_i, t_i))$$

- where $r_1(x_i, c_i, t_i)$ is the predictor encounter probability and $logit^{-1}(a)$ is the logistic
- 57 function, and:

58
$$r_2(x_i, c_i, t_i) = \log^{-1}(p_2(x_i, c_i, t_i))$$

- where $r_2(x_i, c_i, t_i)$ is the predicted biomass density for positive catch rates and $log^{-1}(a)$ is
- the exponential function. Alternatively, ObsModelp[2]=1 corresponds to a "Poisson-process"
- 61 link function that approximates a Tweedie distribution:

62
$$r_1(x_i, c_i, t_i) = 1 - exp(-\exp(p_1(x_i, c_i, t_i)))$$

- where $r_1(x_i, c_i, t_i)$ is the predictor encounter probability and $1 exp(-\exp(a))$ is a
- 64 complementary log-log link, and:

65
$$r_2(x_i, c_i, t_i) = \frac{\exp(p_1(x_i, c_i, t_i))}{r_1(x_i, c_i, t_i)} \times \exp(p_2(x_i, c_i, t_i))$$

- where $r_2(x_i, c_i, t_i)$ is the predicted biomass density for positive catch rates. In this "Poisson-
- process" link function, $\exp(p_1(x_i, c_i, t_i))$ is interpreted as the density in number of
- 68 individuals per area, and $\exp(p_2(x_i, c_i, t_i))$ is interpreted as the average weight per
- 69 individual.

70

Observation models:

- 71 There are different user-controlled options for observation models for positive catch rates.
- # Control observation error
- 73 ObsModel = c(2,0)

74

where ObsModel[1] controls the probability density function used for positive catch rates (see ?Data_Fn for a list of options). VAST then calculates the probability of data as:

77
$$\Pr(b_i = B) = \begin{cases} 1 - r_1(x_i, c_i, t_i) & \text{if } B = 0 \\ r_1(x_i, c_i, t_i) \times g\{B | w_i \times r(x_i, c_i, t_i), \sigma_m^2(c)\} & \text{if } B > 0 \end{cases}$$

- where $g\{B|w_i \times r(x_i, c_i, t_i), \sigma_m^2(c)\}$ is a probability density function for positive catch rates
- 79 with expectation $w_i \times r(x_i, c_i, t_i)$ and dispersion $\sigma_m^2(c)$, where dispersion parameter $\sigma_m^2(c)$
- varies among categories by default.

81 Settings regarding spatial domain

- 82 VAST approximates spatial and spatio-temporal variation as being piecewise-constant. To
- 83 do so, the user specifies n_x:
- 84 # Number of knots
 85 n x = 1000

- VAST then uses a k-means algorithm to identify the location of n_x knots to minimize the total distance between the location of available data and the location of the nearest knot. This distributes knots as a function of the spatial intensity of sampling data.
- VAST then uses a stochastic partial differential equation (SPDE) approximation to the probability density function for spatial and spatio-temporal variation (Lindgren et al. 2011).

 This SPDE approximation involves generating a triangulated mesh that has a vertex of a
- 93 triangle at each knot, and VAST generates this triangulated mesh using package R-INLA
- 94 (Lindgren 2012). Outputs from this triangulated mesh can then be used to calculate the
- 95 precision (inverse-covariance) matrix for a multivariate normal probability density function
- 96 for the value of a spatial variable at each mesh vertex. Specifically, the correlation
- 97 $\mathbf{R}_1(s, s+h)$ between location s and location s+h for spatial and spatio-temporal terms
- 98 included in the first linear predictor is approximated as following a Matern function:

99
$$\mathbf{R}_1(s, s+h) = \frac{1}{2^{\nu-1}\Gamma(n)} \times (\kappa_1|h\mathbf{H}|)^n \times K_{\nu}(\kappa_1|h\mathbf{H}|)$$

where **H** is a two-dimensional linear transformation representing geometric anisotropy (with a

determinant of 1.0), ν is the Matern smoothness (fixed at 1.0), and κ_1 governs the decorrelation

distance for that first linear predictor (κ_2 is also separately estimated for the second linear predictor).

By default, the two degrees of freedom in **H** are estimated as fixed effects, but the user can specify

isotropy (i.e., $\mathbf{H} = \mathbf{I}$) by specifying:

```
# Turn of geometric anisotropy
Data = Data_Fn( ..., Aniso=FALSE )
```

109

115

116

117

118

119

121

VAST then specifies that the spatial and spatio-temporal Gaussian random fields each have a variance of 1.0. By default VAST specifies these as follows:

110
$$\omega_1(\cdot, f) \sim MVN(\mathbf{0}, \sigma_{\omega_1}^2 \mathbf{R}_1)$$

111
$$\omega_2(\cdot, f) \sim MVN(\mathbf{0}, \sigma_{\omega_1}^2 \mathbf{R}_2)$$

112
$$\varepsilon_1(\cdot, f, t) \sim MVN(\mathbf{0}, \sigma_{\varepsilon_1}^2 \mathbf{R}_1)$$

113
$$\varepsilon_2(\cdot, f, t) \sim MVN(\mathbf{0}, \sigma_{\varepsilon_2}^2 \mathbf{R}_2)$$

where $\omega_1(\cdot, f)$ is the vector formed when subsetting $\omega_1(s, f)$ for a given f, and $\sigma_{\omega_1}^2$ is the

variance of $\omega_1(s, f)$, where other parameters are defined similarly. Specifying a variance of

1.0 ensures that the covariance among categories is defined by the loadings matrix for that

term. However, VAST allows spatio-temporal variance to be specified differently as

discussed in the section titled "Structure on parameters among years".

Structure on parameters among years:

There are different user-controlled options for specifying structure for intercepts or spatio-

temporal variation across time, using input:

```
# Control autoregressive structure for parameters over time
RhoConfig = c("Beta1"=0, "Beta2"=0, "Epsilon1"=0, "Epsilon2"=0)
```

- By default (when RhoConfig[1]=0 and RhoConfig[2]=0) the model specifies that each
- intercept $\beta_1(t)$ and $\beta_2(t)$ is a fixed effect. However, other settings specify the following
- 127 structure:

128
$$\beta_1(t+1) \sim Normal(\rho_{\beta_1}\beta_1(t), \sigma_{\beta_1}^2)$$

129
$$\beta_2(t+1) \sim Normal(\rho_{\beta 2}\beta_2(t), \sigma_{\beta 2}^2)$$

- where RhoConfig[1] controls the specification of $\rho_{\beta 1}$:
- 131 1. Independent among years RhoConfig[1]=1 specifies $\rho_{\beta 1}=0$
- 132 2. Random walk RhoConfig[1]=2 specifies $\rho_{\beta 1}=1$
- 3. Constant intercept RhoConfig[1]=3 specifies $\rho_{\beta 1}=0$ and $\sigma_{\beta 1}^2=0$ (i.e., $\beta_1(t)$ is
- 134 constant for all t)
- 4. Autoregressive RhoConfig[1]=4 estimates $\rho_{\beta 1}$ as a fixed effect
- and settings are defined identically for RhoConfig[2] specifying $\rho_{\beta 2}$.
- By default (when RhoConfig[3]=0 and RhoConfig[4]=0) the model specifies that each spatio-
- temporal random effect $\varepsilon_1(s, f, t)$ and $\varepsilon_2(s, f, t)$ is independent among years. However,
- other settings specify the following structure

140
$$\varepsilon_1(s, f, t+1) \sim MVN(\rho_{\varepsilon_1} \varepsilon_1(s, f, t), \sigma_{\varepsilon_1}^2 \mathbf{R}_1)$$

141
$$\varepsilon_2(s, f, t+1) \sim MVN(\rho_{\varepsilon_1} \varepsilon_2(s, f, t), \sigma_{\varepsilon_2}^2 \mathbf{R}_2)$$

- where RhoConfig[3] controls the specification of $\rho_{\varepsilon 1}$:
- 143 1. Random walk RhoConfig[3]=2 specifies $\rho_{\varepsilon 1}=1$
- 144 2. Autoregressive RhoConfig[3]=4 estimates $\rho_{\varepsilon 1}$ as a fixed effect
- and settings are defined identically for RhoConfig[4] specifying $\rho_{\varepsilon 2}$.
- 146 Settings regarding derived quantities
- 147 After a nonlinear minimizer has identified the value of fixed effects that maximizes the
- Laplace approximation to the marginal likelihood, Template Model Builder predicts the value

- of random effects that maximizes the joint likelihood conditional on these fixed effects.
- Estimated values of fixed and random effects are then used to predict density d(x, c, t) for :

151
$$d(x,c,t) = r_1^*(x,c,t) \times r_2^*(x,c,t)$$

- where $r_1^*(x, c, t)$ and $r_2^*(x, c, t)$ are identical to the values specified previously, except that
- catchability variables are excluded from their computation (i.e., $\delta_1(v, f) = 0$ and $\lambda_1(k) = 0$,
- 154 etc.)

- By default, density is used to predict total abundance for the entire domain (or a
- subset of the domain) for a given species:

157
$$I(c,t,l) = \sum_{x=1}^{n_x} (a(x,l) \times d(x,c,t))$$

- where a(x, l) is the area associated with extrapolation-cell x for index l. The user can also
- specify additional post-hoc calculations via input:
- # Control observation error
- RhoConfig = c("SD_site_density"=0, "SD_site_logdensity"=0, "Calculate_Range"=0,
- "Calculate evenness"=0, "Calculate effective area"=0, "Calculate Cov SE"=0,
- 'Calculate Synchrony'=0, 'Calculate Coherence'=0)
- 165 1. Distribution shift RhoConfig[3]=1 turns on calculation of the centroid of the
- population's distribution:

$$Z(c,t,m) = \sum_{x=1}^{n_x} \frac{\left(z(x,m) \times a(x,1) \times d(x,c,t)\right)}{I(c,t,1)}$$

- where z(x, m) is a matrix representing location for each knot (by default z(x, m) is the
- location in Eastings and Northings of each knot), representing movement North-South
- and East-West).
- 2. Range expansion RhoConfig[5]=1 turns on calculation of effective area occupied. This
- involves calculating biomass-weighted average density:

 $\bar{d}(c,t,l) = \sum_{x=1}^{n_x} \frac{a(x,l) \times d(x,c,t)}{I(c,t,l)} d(x,c,t)$ 173 Effective area occupied is then calculated as the area required to contain the population at 174 this average density: 175 $A(c,t,l) = \frac{I(c,t,l)}{\bar{d}(c,t,l)}$ 176 Works cited 177 Lindgren, F. 2012.
